

Finding Shower Vertices using a CNN

Leigh Whitehead

ProtoDUNE Reconstruction Meeting

28/06/17

Introduction

- One of the trickier problems to solve in LAr-TPC reconstruction has been the accurate identification of shower vertices
 - This is vital for high-level tasks such as reconstructing pi-zeros and performing electron / gamma separation
- Seeing the success of the track / shower CNN, we have started to develop a CNN to search for shower vertices.
- Still quite early in the development, but I wanted to outline the ideas and very preliminary results

A question of training

- The first job is to define the signal that we need to train on
- I have produced a number of particle-gun pi-zero decays in the TPC
 - Energy of 1 GeV +/- 0.5 GeV
 - This is actually a bit high on average for the energies we can expect, but was just an initial choice
- Then use truth information to select out those spatial points where a gamma conversion occurred
 - Gamma required to have at least 40 MeV energy to be considered

Gamma conversions

- Look at the number of **neighbouring hits** to each **gamma conversion** in a 7x7 grid, and two populations appear:

Clear gamma conversions
at the beginning of a shower

Gamma conversions

- We want to select this population of gamma conversions at the start of the showers

- Optimised cut selects those with between 5 and 14 neighbours.
 - Optimised using the two Gaussian functions and $S/\sqrt{S+B}$ F.O.M.

Gamma conversions

- Example of selected gamma conversions:

Gamma conversions

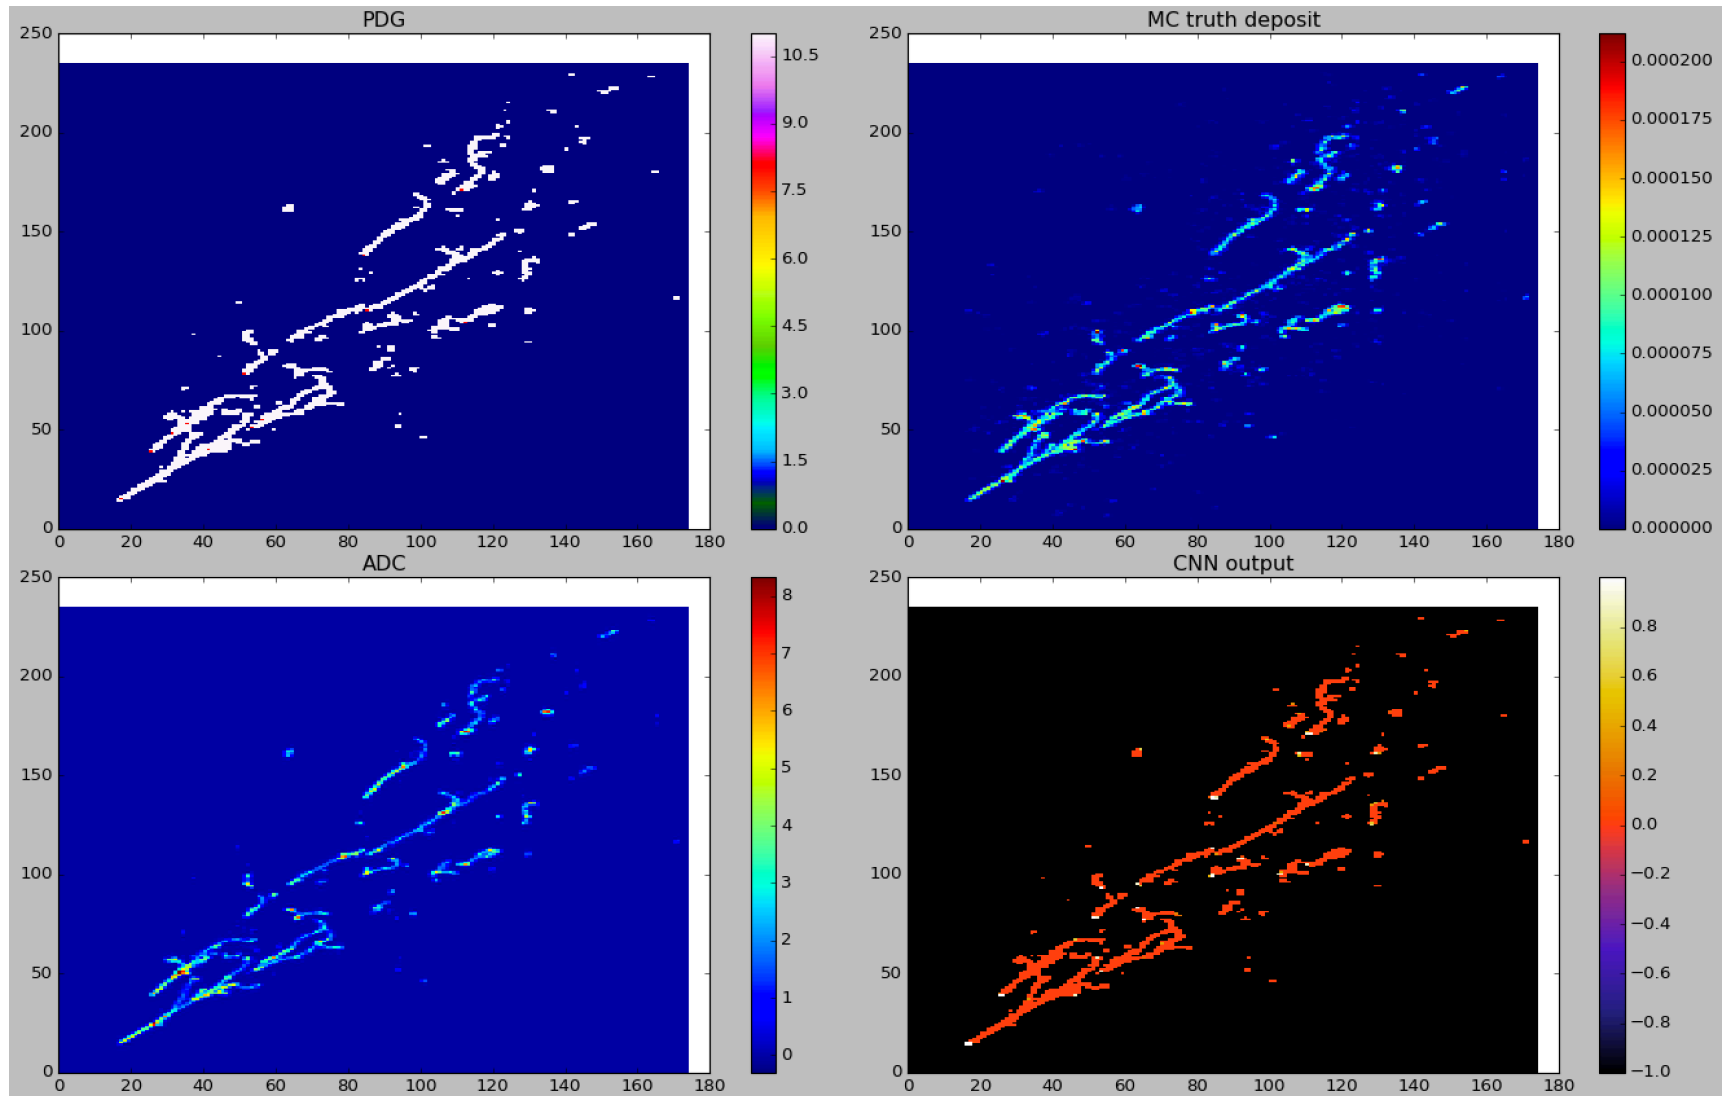

- Example of selected gamma conversions:

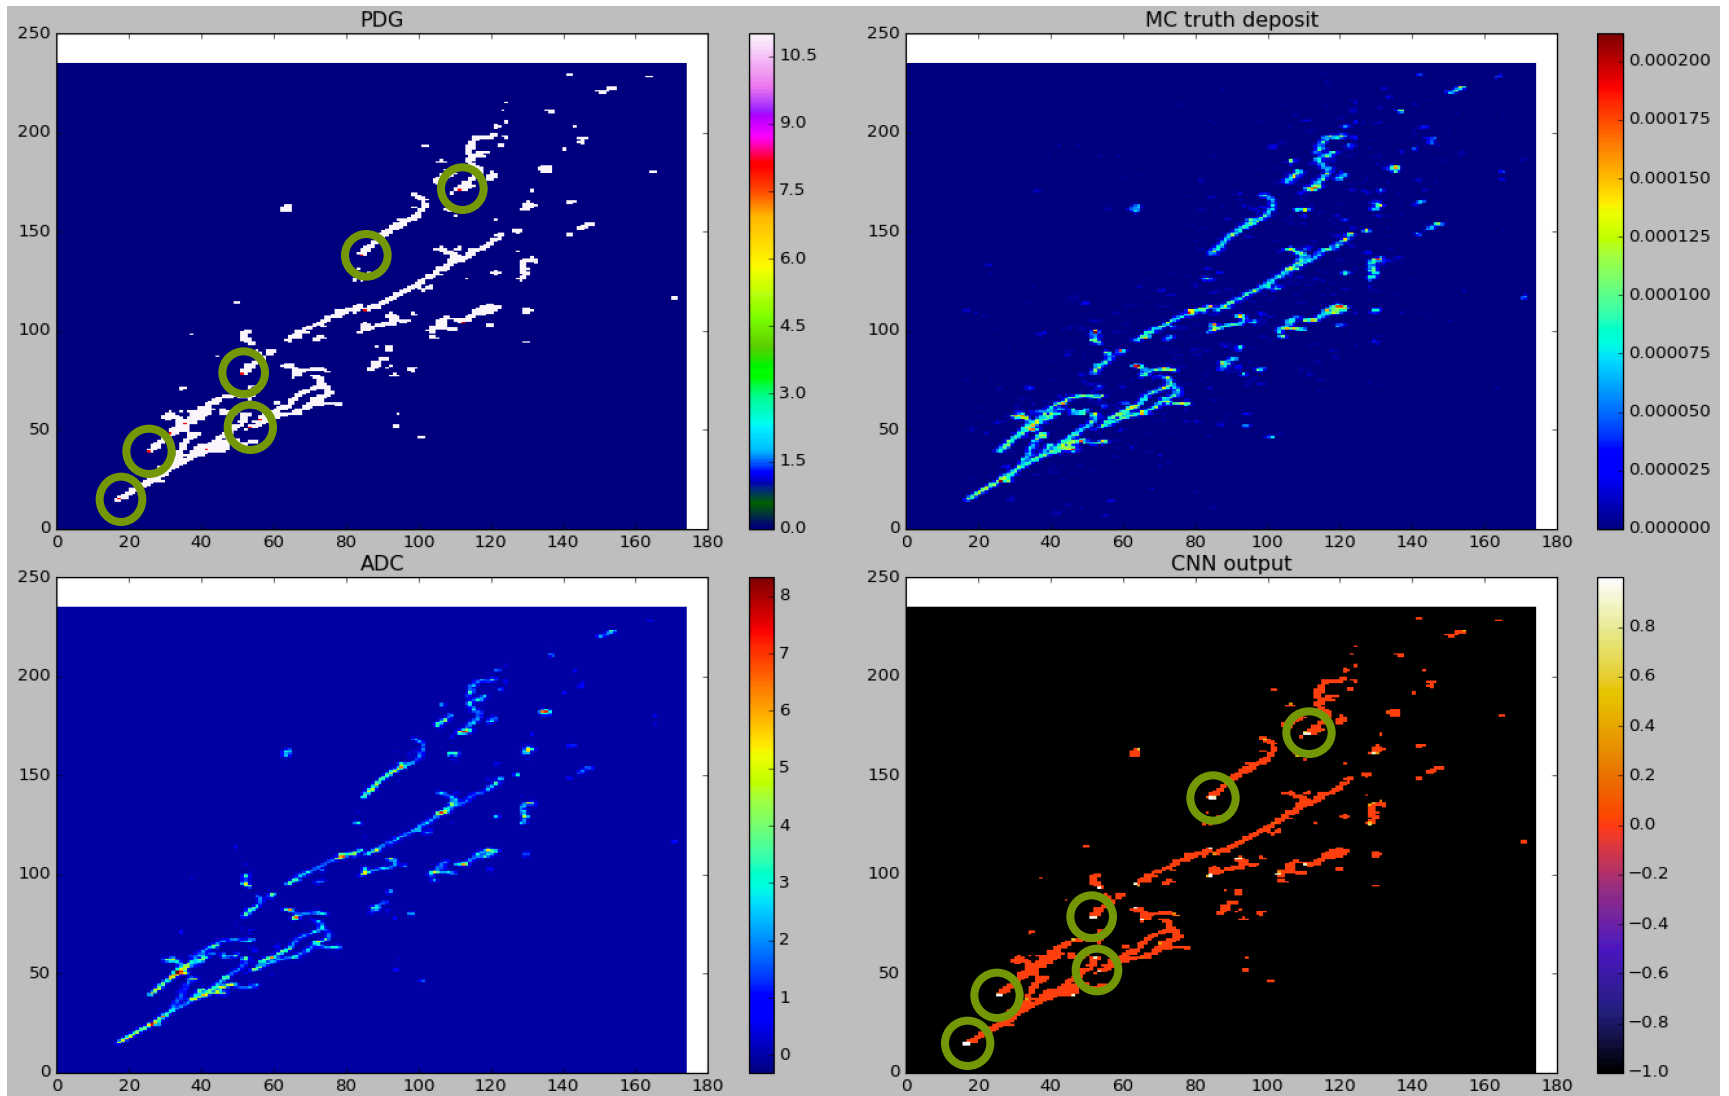

A question of training

- The CNN is trained using the definition of signal given by the number of neighbours
- Background patches for the training come from various parts of the images that are not defined as signal
- Second training was using 300,000 patches
- Network output from 0 to 1, with 1 most likely to be a gamma conversion

Example Output (3)

Example Output (3)

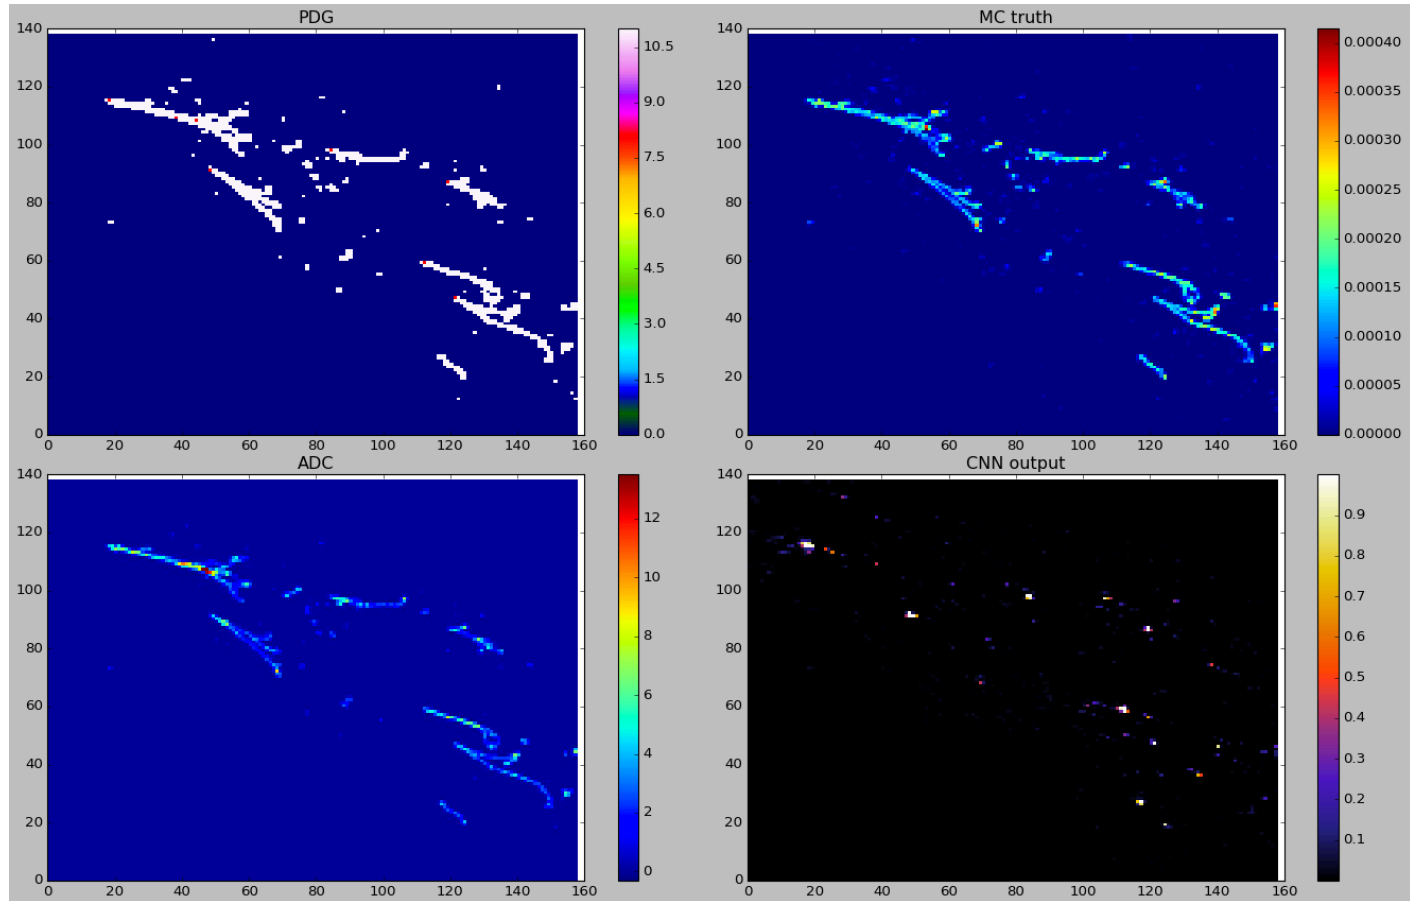

Summary

- Work has begun on training a CNN to identify shower vertices
 - Use the number of neighbours of photon conversions to define the signal
- Initial scans of event displays look promising
 - Some false positives at the end of electron tracks. Will try to include a sample of these labelled as background.
- Now need to work on performance metrics for quantitative measures of how well the network is performing
- Think how to integrate it with the track / shower CNN

Example from first training

- Bright spots in the bottom right identify regions considered likely to be gamma conversion points

Example from first training
